

1 Security Case

ViewModel is very important for **security reasons**.

- It prevents sending sensitive data from the database to the view.
- For example, the `User` model may contain:
 - Password
 - Role
 - Internal IDs

If we send the full model to the view, this data could be exposed.

Instead, we create a ViewModel that only includes safe fields like:

- Name
- Email

This protects the system from **data leakage and hacking risks**.

2. Display Only Needed Data (Separation of Concerns)

Sometimes the model has many fields, but the view only needs a few.

- Sending the full model is unnecessary and messy.
- ViewModel allows us to send **only what the UI needs**.

Example:

- Model has 10 fields
- View needs only 3

ViewModel makes the code:

- Cleaner
 - Easier to maintain
-

3. Combining Multiple Models in One View

Sometimes one view needs data from **more than one table/model**.

Example:

- Department + Students

Instead of sending multiple models, we create one ViewModel:

```
class DepartmentWithStudentsVM
{
    public string DepartmentName { get; set; }
    public List<Student> Students { get; set; }
}
```

This makes it easier to:

- Organize data
- Pass it to the view
- Avoid confusion
